# Supplementary Feed Crops for 1935

GEO. M. BRIGGS

by courtesy of

*Extension Service of the College of Agriculture, The University of Wisconsin, Madison*

**W**HEN THE regular hay acreage is short or has been impaired by freezing, some of the following crops can be grown.

## Soybeans Are Popular

Soybean hay is about equal to alfalfa in feeding value and ready to harvest the same season it is planted. This crop is adapted best to soils and seasons when and where corn does well and no special machinery is required for planting, caring for, or harvesting the crop.

One and one-half to three tons of soybean hay can be harvested to the acre. The yield will depend upon the fertility of the soil, moisture, and good growing weather. The lighter yields come only from unfertilized, runout soils or where weeds are not controlled.

Soybeans are adapted to most soils. While they are not sensitive to acidity, yet they do best if lime is plentiful. The plant thrives on low soils but if they are limited in potash a small amount of manure or an application of 100 to 150 pounds an acre of a potash fertilizer is desirable.

The soybean is a double purpose crop. It can be used as a "pinch hitter" when alfalfa fails as a field or in spots; and is oftentimes used after an early crop of peas or after an early crop of hay has been harvested. Corn planting time is the proper time for planting soybeans. The later planting will not result in as high yields but will allow for weed killing before planting.

## Suggestions on Planting

On clean soils or on new or soddy fields, solid planting with grain drill requires less labor, and results in a good quality hay. On old, weedy or thin soils, planting in rows with a grain drill with some spouts closed, or with a sugar beet drill, or with a corn planter, at regular width or narrowed down, insures as high yield of cleaner hay at less expense of seed than would be obtained if planted solid. In planting solid, use at least two bushels of seed to the acre. In planting in rows, 30 to 60 pounds are required, depending upon the distance between rows.

*First*, plant shallow, about as one would for corn.

*Second*, inoculate the seed for increasing yields, and quality of hay and fertility of soil. *Third*, use good seed. If doubtful, test. *Fourth*, use enough seed. Drop soybeans

1 to 1½ inches apart in the row—the heavier the soil the closer together.

Plant soybeans on a well-prepared seed-bed as for corn. Use the common grain drill when planting solid, and in planting in rows use a corn planter, beet drill, or grain drill with some spouts closed. Delayed planting in order to prepare a seed bed better is preferable to planting early on an unprepared weedy seed bed. When the plants are three to five inches high the use of a rotary hoe or common harrow cross-wise or diagonally of the field after morning dew is off, breaks up the crust and destroys many small weeds.

## Made Like Any Other Hay

A high quality of hay is made from soybeans at almost any time in their growth. It is best not to let them ripen too much before cutting for hay. However, as long as the leaves do not dry off perhaps the value of the crop as hay has not been impaired if pods show some good sized beans.

In making soybean hay, good curing weather is just as important as the stage of maturity. Cutting soybeans before the last week in August gives better assurance of suitable drying weather. The best hay is made when the pods are full size, but only small beans in them, and when the leaves are all green and still adhering to the plant. On late planted fields or in later maturing varieties, the plant may be in the blossom stage at proper cutting time.

Soybean hay is handled like any other hay crop with mower, side delivery rake, and hay loader. Some farmers prefer curing the hay in cocks, leaving it ten days or longer. In heavy crops and in late cuttings it may need to lay in the swath a day or more longer than lighter yielding hays and early cut crops.

To prevent leaves from shattering, any handling of the crop can best be done in the forenoon just after the surplus dew has dried off. If put in cocks while leafy, rains will not enter to any great extent and a fine palatable hay will result even if it is left cut for ten days or longer. As with other hays cured in cocks, turning these cocks over a few hours before hauling is beneficial.

The use of a binder in cutting soybeans and shocking in long shocks, of four to six bundles, is meeting favor. If weather remains damp at harvest time, mowing in barn is essential and it often might be wise to stack out doors in narrow stacks, having protection of other hay over the stack.
